ROAD SAFETY INTELLIGENCE

Road Collision Risk & Spatial Inequality

Where is road risk high after exposure, and where is collision burden socially concentrated?

↻ Reset filters

YEAR: All

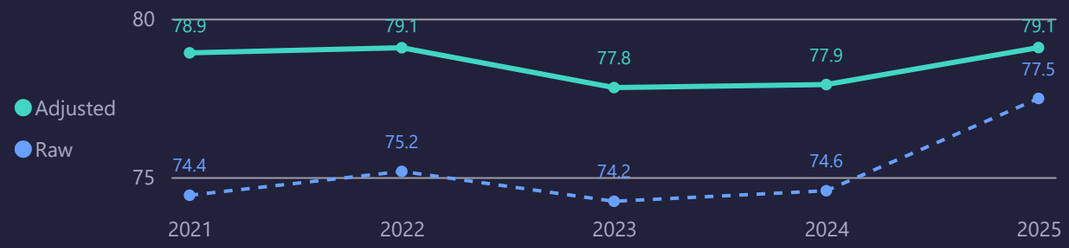

RISK METRIC: Adjusted expected KSI

ⓘ Resident-normalised rates show community burden, not traffic exposure.

Reported collisions	Adjusted KSI / bn vehicle miles	Deprivation burden ratio	Traffic-exposure coverage
513,801	78.6	2.03x	99.98%
	▲ 0.8% vs previous year		

NATIONAL TREND

KSI risk after accounting for traffic exposure

DECISION SIGNAL

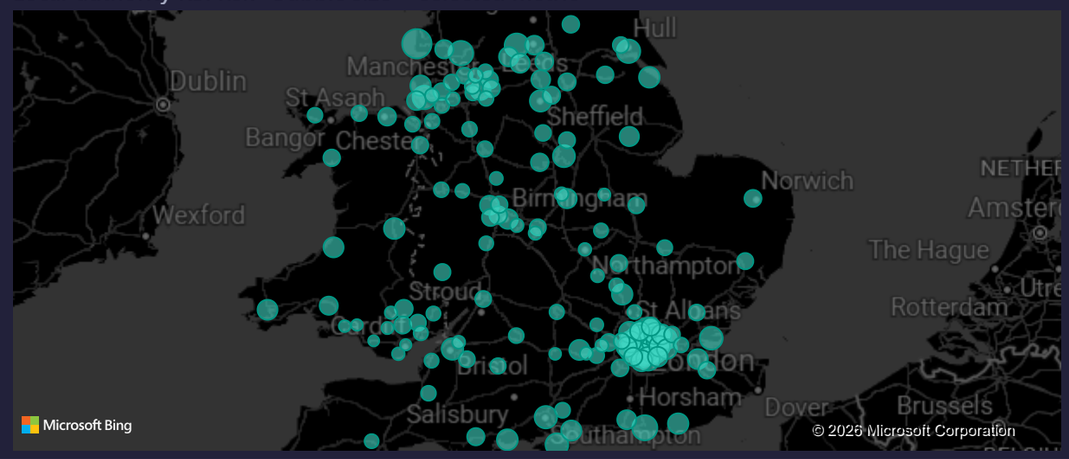

Two problems require two intervention tracks

2.03× Five-year collision burden: most deprived versus least deprived neighbourhoods.

30.9 Adjusted expected KSI per 100 rural collisions in the selected period.

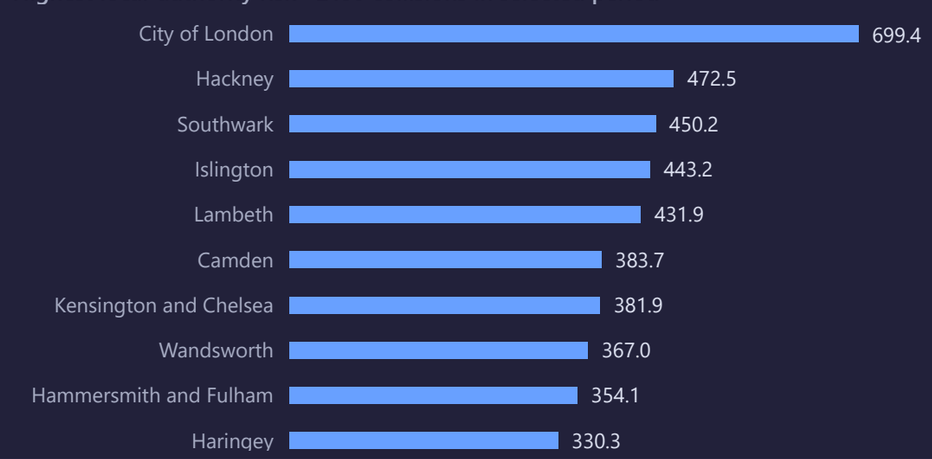

GEOGRAPHIC DISTRIBUTION

Local-authority KSI risk · Bubble size = selected metric

INVESTIGATION QUEUE

Highest local-authority risk · ≥100 collisions in selected period

ROAD SAFETY INTELLIGENCE

Road Collision Risk & Spatial Inequality

Separate community burden from traffic exposure before setting place-based priorities.

↻ Reset filters

YEAR

All

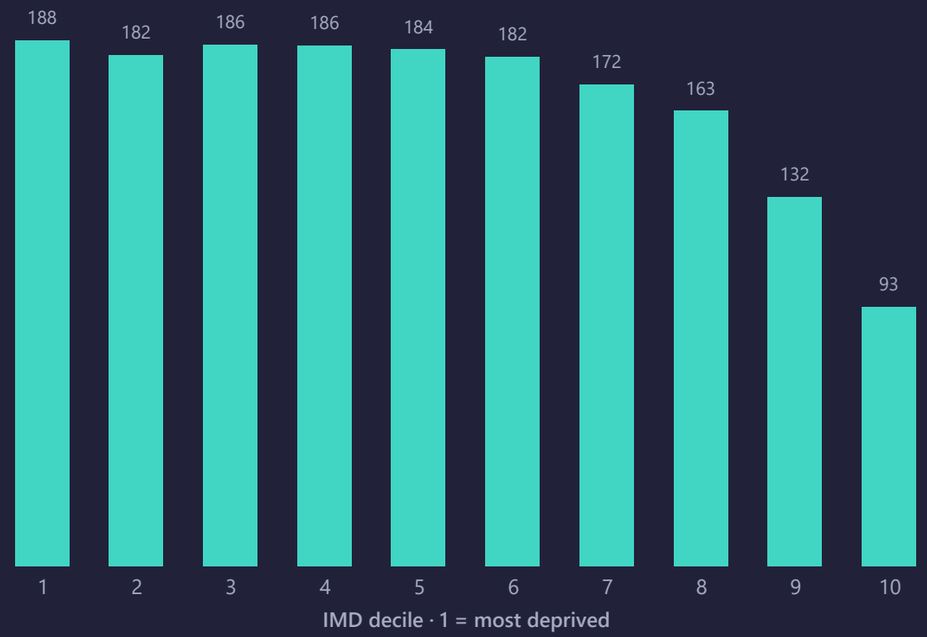

SPATIAL INEQUALITY

The deprivation gap reflects collision occurrence rather than conditional severity.

ⓘ Resident-normalised rates show community burden, not traffic exposure.

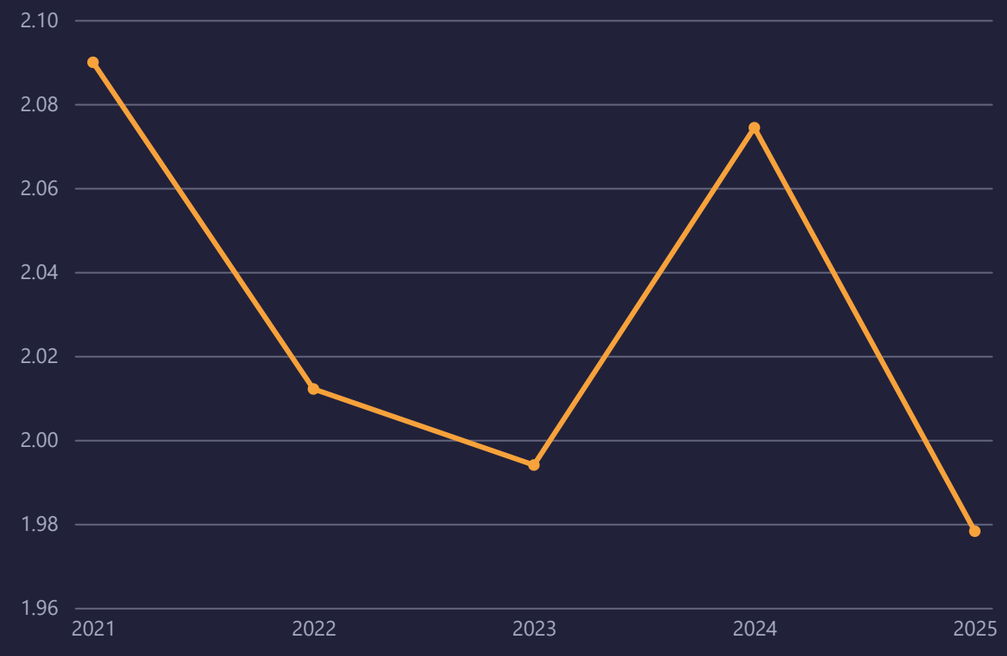

Collision burden by deprivation decile

Collisions per 100k residents per year

Annual most-to-least deprived gap

Zoomed scale · 1.00 = parity

INTERPRETATION

The inequality signal is persistent, but it is not an exposure-adjusted road-risk estimate.

Use this view to prioritise neighbourhood diagnosis and place-based prevention. Do not use it to claim that deprivation causes collisions or that residents themselves generated the traffic exposure.

ROAD RISK & SEVERITY

Context changes the consequences of a collision

Urban vs rural severity

Conditional severity peaks on 60 mph roads

INTERPRETATION

Speed limit is informative, but not a sufficient causal explanation.

Conditional severity peaks on 60 mph roads and falls on 70 mph roads. Road class, traffic separation, junction context and road-user mix should be modelled jointly before recommending a specific intervention.

Exposure scenario coverage

MODEL GUARDRAILS

Local-authority traffic coverage

99.98% — Authority-year vehicle miles

England-to-IoD join

100% — Applicable English collision records

AADF ≤100m coverage

11.2% — Eligible numbered-road collisions

Raw vs adjusted rank correlation

0.991 — 2025 Spearman ρ

LIMITATION

AADF point matches are a sensitivity diagnostic, not a link-level absolute risk denominator.

Do not use the AADF coverage scenarios to publish absolute road-link risk rates until road-segment geometry matching is available.
